## 1 The Church-Turing Thesis

### 1.1 Turing machines

#### 1.1.1 Introduction

TM is a **much more powerful model**, it can do everything that a general computer can do.

Nonetheless, even a Turing machine cannot solve certain problems. These problems are beyond the theoretical limit of computation.

- Uses an **infinite tape** as its unlimited memory. It has a tape head that can read and write symbols and move around on the tape.

Initially the tape contains only the **input string**, and is blank everywhere else.

If the machine needs to store some information, it may **write information** on the tape.

To read the information *it has written*, the machine can move its head back over it.

The machine continues computing until it decides to produce an output. The outputs *accept* and *reject* are obtained by entering designated accepting and rejecting states.

#### 1.1.2 Differences between FA & TM

1. A tm can both read and write the tape.
2. The read-write head can move both to the left and to the right.
3. The tape is **infinite**

4. The special states for rejecting and accepting take effect immediately.

### 1.1.3 A example: TM to test membership of $\{w\#w \mid w \in \{0,1\}^*\}$

The language B means a string comprises two identical strings separated by a # symbol.

Imagine you are on a mile long road with inputs on the ground. How to determine the input is in B? **Zig-zag** to the corresponding places on the two sides of the # and determine whether they match, is a obvious strategy.

And we design a machine to work in that way.  $M_1 =$  "On input string  $w$

1. Zig-zag across the tape to corresponding positions on either side of the # symbol to check whether these positions contain the same symbol. If they do not, or if no # is found, **reject**. Cross off symbols as they are checked to keep track of which symbols correspond.
2. When all symbols to the left of the # have been crossed off, check for any remaining symbols to the right of the #, if any symbols remain, *reject*; otherwise, *accept*.

"

### 1.1.4 Formal Definition of a Turing Machine

The heart: transition function  $\sigma$  For a Turing machine,  $\sigma$  takes the form:  $Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}$ . That is, when the machine is in a certain state  $q$  and the head is over a tape square containing a symbol  $a$ , and if  $\sigma(q, a) = (r, b, L) \rightarrow$  The machine writes the symbol  $b$  replacing the  $a$ , and goes to state  $r$ . The third component is either  $L$  or  $R$  and indicates whether the head moves to the left or right after writing. In this case, the  $L$  indicates a move to the left.

A Turing machine is a 7-tuple,  $(Q, \Sigma, \Gamma, q_0, q_{\text{accept}}, q_{\text{reject}}, \sigma)$ , where  $Q, \Sigma, \Gamma$  are all finite sets and

1.  $Q$  is the set of states,
2.  $\Sigma$  is the input alphabet not containing the blank symbol
3.  $\Gamma$  is the tape alphabet, where  $\sqcup \in \Gamma$  and  $\sqcup \notin \Sigma$ ,
4.  $\sigma : Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}$  is the transition function,
5.  $q_0 \in Q$  is the start state,

6.  $q_{\text{accept}}$  is the accept state, and

7.  $q_{\text{reject}}$  is the reject state, where  $q_{\text{reject}} = q_{\text{accept}}$  .

**1.1.5 More on the definition:**
